Noble Gas Anesthetics and Immobilizers Show Different Binding Distributions to KcsA Channel

Masayuki Ozaki, Tomoyoshi Seto.

Shiga University of Medical Science, Otsu, Japan.

Neuronal ion channel is prominent candidate of molecular target anesthesia, but still not yet identified. Using KcsA potassium ion channel as model, anesthetic-protein interactions are investigated. We choose xenon, krypton and argon as anesthetics, which have simple structure. Neon and helium were also studied, which are structurally similar to anesthetics but do not have the anesthetic effects predicted by the Overton-Meyer rule (nonimmobilizers). Using computer simulation these binding sites of KcsA are searched. From the noble gas-KcsA complex structure we discuss binding characteristics of anesthetic and nonimmobilizer. **Methods:** 1k4c (PDB) was used as KcsA structure. Cavities in KcsA was searched with alpha-site finder (geometric search) in Molecular Operating Environment 2007.0902 (MOE, Chemical Computing Group, Canada), that is candidates of binding site of noble gas. Obtained dummy atom from alpha-site finder was used as initial position. Noble gas binding position was searched with energy minimization around initial position. MMFF94x was used for forcefield. **Results:** Binding energy of Xe, Kr, Ar were -8 to -4 kcal mol $^{-1}$, whereas Ne and He were -2 kcal mol $^{-1}$. Xe, Kr, Ar bound to gating region first, then they distributed to inter-helical space of transmembrane region. Ne bound to inter-helical space first, then to the gating region. Energy gaps of inter-helical sites were small, so noble gas was consider to be possible to transit from site to site with thermal energy. We considered that inter-helical binding have small position specificity (nonspecific binding). Ne and He binding distributed inter-helical sites, the energy gaps were further small. They showed nonspecific binding. Anesthetics and nonimmobilizers of noble gases show different binding distribution to KcsA. We speculate that pharmacological difference of anesthetic and nonimmobilizer originates from the difference in binding distribution of these substances.

Ligand Induced Conformational Changes in GPCRs: Insight Into the Activation of Rhodopsin and β -adrenergic Receptors

Supriyo Bhattacharya, Nagarajan Vaidehi.

City of Hope National Medical Center, Duarte, CA, USA.

Signal transduction in GPCRs is initiated by ligand binding at the extracellular domain of the receptor. Recent experimental evidences indicate that structurally different ligands with varied efficacies stabilize distinct receptor conformations. Understanding the relationship between ligand structure and the stabilized receptor conformation is critical in designing GPCR drugs with functional selectivity for a particular signaling pathway. We recently developed a computational method (LITiCon) to study the ligand induced transmembrane conformational changes in GPCRs. Using this method, we have predicted the active conformation of bovine rhodopsin stabilized by the full agonist all-trans retinal. The major conformational changes upon activation are the straightening of the TM6 kink and tilting of the intracellular end of TM5 towards TM6. These predictions are in agreement with the recently published crystal structure of ligand-free opsin, which is believed to be in a partially active conformation. We then study the conformational changes in human β -adrenergic receptors induced by full and partial agonists as well as inverse agonists. In the predicted conformation of the β_2 -adrenergic receptor stabilized by the full agonist norepinephrine, the three serines on TM5 come inside the binding pocket and the extracellular end of TM6 tilts towards TM3. These changes lead to shrinking of the norepinephrine binding pocket thus tightening the protein-ligand contacts. A new HB between N293 on TM6 and the β -OH of norepinephrine is formed in the norepinephrine stabilized conformation, which was not possible in the inactive conformation. Virtual ligand screening of the inactive receptor conformation shows higher selectivity for antagonists compared to agonists, whereas that of the norepinephrine stabilized conformation shows higher selectivity for agonists compared to antagonists. These results along with new insights into the ligand specificities between β_1 and β_2 receptor subtypes will be presented.

Structural Determinants Of Antibiotic And β -lactamase Diffusion Through Bacterial Porins

Amit Kumar, Eric Hajjar, Paolo Ruggerone, Matteo Ceccarelli.

University of Cagliari, Monserrato, Italy.

General diffusion porins such as OmpF and OmpC, located in the outer membrane of bacteria, represent the main entry point for different classes of anti-

biotics. Bacteria can resist the action of antibiotics by underexpressing and/or mutating porins. Nowadays the problem of bacterial resistance calls for new antibiotics.

Another way bacteria exhibit resistance is by expressing enzymes that degrade antibiotics, such as β -lactamase that act on β -lactam antibiotics. Inhibitors of such enzymes are prescribed in combination with antibiotics to block β -lactamase and let antibiotics to reach their target. Again, β -lactamase inhibitors have to diffuse through porins in order to reach their target. Understanding how antibiotics and β -lactamase inhibitors diffuse through porins would help to design new molecules with improved permeation properties, solving this problem of resistance.

To investigate the diffusion process of molecules through bacterial porins we used classical MD simulations using OmpF in monomeric and trimeric form. Indeed, as showed experimentally, diffusion is controlled mainly by interaction at the molecular scale. However the high level of accuracy of MD represents also a limitation for simulations to reach the typical time scale of diffusion, from microsecond to millisecond. To overcome this problem we used an acceleration scheme, metadynamics, that allow extending simulations time to biological time scale.

From MD simulations we identified the structural determinants that play a key role in the diffusion process : (i) Flexibility of the molecule diffusing and porin (ii) particular localisation of charged residues (iii) presence of hydrophobic pockets. Further, we observed reciprocal influence of each monomer, in particular in the external loops and the constriction region. We compared diffusion of different antibiotics through various classes of porins, to understand better the problem of bacterial resistance to antibiotics.

Conformational Transitions and Proton Conduction in the Multidrug Efflux Pump AcrB

Nadine Fischer, Christian Kandt.

University of Bonn, Bonn, Germany.

The increasing problem of multi-drug resistance (MDR) in cancer therapy or bacterial infections is to a large degree caused by multi-drug efflux pumps in pathogenic cells. In *Escherichia coli*, a major resistance mechanism against antibiotics is based on a tripartite multi-drug export complex comprising the inner membrane translocase AcrB, the membrane-fusion protein AcrA and the outer-membrane channel TolC. AcrB functions as the engine of this complex, using proton motive force to expel a wide variety of unrelated toxic compounds such as antibiotics, disinfectants or detergents. The molecular mechanisms of how proton conduction through AcrB is coupled to drug expulsion are not fully understood yet. Here we report a combination of normal mode analysis (NMA) and molecular dynamics (MD) simulation to investigate conformational transitions occurring in the AcrB reaction cycle and to identify residues crucial for proton conduction. In the crystallographic structure of AcrB each monomer is trapped in a different conformation, representing consecutive states in the transport mechanism. Applying the elastic network NMA variant of minimum action pathway (Kim et al. 2002), we computed transitions between these states. The resulting c-alpha trajectories were then converted back to all atom in an approach of steered energy minimization. We also performed multi-copy MD simulations of AcrB embedded in a phospholipid/water environment using the GroMACS simulation package. Mapping the proton conduction pathway was done on the basis of protein-internal water dynamics and monitoring their frequency of forming hydrogen bonds to adjacent residues.

Dynamics Of Water Molecules In Bacteriorhodopsin Mutants

Mihnea Dulea¹, Ana-Nicoleta Bondar².

¹'Horia Hulubei' National Institute for Physics and Nuclear Engineering, Magurele, Romania, ²University of California at Irvine, Department of Physiology and Biophysics, Irvine, CA, USA.

Water molecules are essential for the functioning of proton-pumping proteins. Bacteriorhodopsin is a light-driven proton pump whose reaction cycle is accompanied by changes in the interactions between the protein and the retinal chromophore with water molecules. Of particular importance is the formation of a chain of water molecules that mediate the reprotonation of the retinal Schiff base from the Asp96 residue. Asp96 is replaced by histidine in channelrhodopsin-1 (G. Nagel et al, *Science* 296, 2395-2398, 2002), and by glutamate in *Neurospora* rhodopsin (Y. Fan, L. Shi & L. S. Brown, *FEBS* 581, 2557-2561, 2007). Significant effects of mutating Asp96 on the proton-pumping kinetics of bacteriorhodopsin, and effects of mutating the corresponding residues in other retinal proteins, have been documented. To understand how replacement of
